TITLE: Proton relaxation in zeolitic water

PERIODICAL: Zhurnal strukturnoy khimii, v. 4, no. 1, 1963,
106-107

TEXT: It is noted that although the structure of many zeolites has been studied in some detail both experimentally and theoretically, there is little information about molecular bonding forces in zeolitic water. This has been largely due to experimental difficulties encountered with chemical and spectroscopic (X-ray and infrared) methods. The present work was undertaken to obtain further information about zeolites and to determine the NMR line widths for artificial zeolites. The following were investigated: KA, NaA, CaA, LiA and MgA. It was found that the derivatives of the absorption lines of KA, CaA and MgA did not exhibit detectable splitting which ascribed to the fact that the specimens had not lower than fourfold symmetry axes and the sorption cavities were nearly spherical. Mea-

sured NMR line widths as functions of the relative amount of water appear to confirm that the spin-spin relaxation time does depend on the relative amount of water as reported by Matyash et al (this journal, 2, 214, 1962). On the other hand the self-diffusion coefficient of water molecules in zeolites is universally proportional to the line width ΔH . The correlation between ΔH and τ_i/τ is shown below

Cation	K	Na	Ca	Li	Mg
$\Delta H \text{ re}$	0.08	0.09	0.17	0.17	0.48
τ_i/τ	0.05	1.46	2.16	3.48	8.63

where τ_i is the mean life of water molecules near the corresponding cation and τ is the corresponding equilibrium value in pure water. There are 2 figures and 1 table.

Phosphate colorimetric method for determining boron. M. L. Tammann and V. I. Prokof'ev. *Zhurn. Nauk. i Tekhn. Zashch. Pat. i Trad. Tov.*, 6 (1951) 69-76 (1952); *Akad. Nauk SSSR, 6* (B) 64 (1952).—The authors proposed a phosphate colorimetric method for determining B based on the method of Dvorak. The B is precipitated as phosphate. The precipitate is filtered, carefully washed, and dissolved in HCl. The P_2O_5 in the solution is determined colorimetrically. From the amount of P_2O_5 present, the amount of B_2O_3 , converted with it is calculated. $(M \cdot H)$.

1946. The testing and adjusting of LVP-4 vacuum presses (S.M.-32).—
M. S. TARASHENKO (*Sib. Keram.*, 7, No. 12, 4, 1950). This vacuum press is intended for the manufacture of hollow blocks, refractories, acid-resistant products, etc. The trial of the first designs of this machine showed its defects, e.g. low efficiency, overfilling of the vacuum chamber with clay, inadequate evacuation of the chamber, marked lamination, a greater density of the core of the pressed product coming from the mouth-piece, mechanical troubles with parts of the press, etc. Attempts to eliminate each deficiency are described in detail, e.g. to combat the overfilling of the vacuum chamber the number of blades on the shaft of the mixer at the entrance of the chamber was increased (from 6 to 12-18). The output thus reached was 2,000-2,500 bricks/hr. Afterwards attempts were made to determine the optimum moisture content of the clay, which greatly affects the efficiency of the press. The overfilling of the vacuum chamber with clay was found to be due to the soaking of water into the chamber at the moment when the vacuum pump was switched off, and the consequent increase in the moisture content. To eliminate this a separator was installed on the piping from the chamber to the pump. A gap between the cone fixed on the mixer shaft and the moving clay was found to be responsible for the poor vacuum. The following steps were then taken: the adjustable bearings were removed; the number of blades fixed to the cone on the mixer shaft was increased (from 6 to 10-12); the safety jacket at the cone worm casing was removed. The vacuum was increased from the original value of 300 mm. Hg to 500 mm. It was observed that the max. vacuum (with the same pump) depends on how tightly the clay seals the chamber, i.e. on the moisture content of clay, and on the rate at which clay passes the ring opening. (9 figs., 1 table.)

BCS

29. The origin of Nodules cracks.— M. S. Tadzhurov (Soviet. Keram., 8, No. 6, 14, 1951). It is stated that the following theory applies to the U.S.A. for S-cracks in bricks. A circular hole is formed in the clay column opposite the base of the nodule. A horizontal crack which extends in the direction of the surface, passes through the oval hole. During the movement of the brick, it is twisted by some rotation, and the oval hole becomes a horizontal crack. This has been subjected to shear stresses. According to Kehler, the formation of the vertical cracks, considered as fracture surfaces, is due to the introduction of certain materials into the clay column and those to which the latter have nothing to do with the determination of the clay mix. These above factors, and the dry sand, therefore, prevent or delay the formation of the nodule cracks. To study how clay is supplied by the nodule during shearing, as many influencing factors

over

as possible were excluded in the following experiments. Clay, after consolidation in the spacer (which consisted of a paraffin spacer, an expansion chamber and a tapered spacer) was extruded by the auger with the die removed. Thus the flow received a direction although the principal factor regulating it was absent and the flow was free. When the clay column movement was observed from the front, it could be clearly seen that this movement is effected in a pulse-like manner, alternately from left and from right. The column was cut into parts and photographs show the origin and development of the crack which with free extrusion causes the column to split in-situ. Moreover, it is seen that, although there is a trace like a hole in the mass, the crack appears and develops independently of it. This hole is a centre to which the cracks lead. It is concluded that one of the main causes of S-cracks are these continuous impacts exerted upon the clay in the spacer. It is assumed that these impacts can be explained by the changes in force of the auger exerted upon the clay combined with the elastic properties of the latter. The force exerted by the rotating blade on the clay is gradually increased to the edge of the blade, behind which it diminishes sharply. During rotation of the blade pressure changes within a circle along a radius from a max. at the wall of the spacer to a min. in the centre. Owing to elastic properties, energy received from the auger blade is accumulated until sufficient to overcome gravity, inertia, pressure and the forces of internal friction. This elastic potential is stated to cause the S-cracks. (12 figs.)

TITLE: Effect of gamma rays, fast neutrons, and ethyleneimine on changeability and chromosome aberrations in potato seedlings

SOURCE: Radiobiologiya, v. 3, no. 3, 1963, 427-430

TOPIC TAGS: gamma rays, fast neutrons, ethyleneimine, chromosome mutations

ABSTRACT: The offspring of hybrids resulting from crossing of cultured and wild species often are resistant to diseases but also display certain negative characteristics acquired from the wild species. The hybrids are crossed repeatedly to eliminate these undesirable characteristics. In this study may be overcome by induced mutation of the chromosome in the hybrid. This difficulty may be overcome by the positive characteristics of the wild species. The hybrids and in the process the positive characteristics are often lost. The chromosome is often increased by 7 to 15% when treated with gamma rays, fast neutrons, and ethyleneimine for 24 hours. Results show that the irradiation energy of the seeds increased by 10% when treated with gamma rays and fast neutrons and decreased by 10% when treated with ethyleneimine. Cytological investigations indicate that gamma rays increase the frequency of mitoses with chromosome aberrations by 11.23 + or - 1.23%, fast neutrons by 7.22 + or - 0.31%

TITLE: A Device for Cutting Out Gaskets.

PERIODICAL: Mashinostroitel', 1959, Nr 7, p 37 (USSR)

ABSTRACT: The described device cuts gaskets out of sheet material, "paronit", cardboard, or rubber. It is used on a drilling machine, attached by a mandrel to the spindle. Its cutting tools are two cutting rollers (Figure 1) cutting on the inner and outer diameter of the gaskets. The rollers can be fixed at different distances from the center, and for cutting material of more than 4 mm thickness, the cutting rollers are replaced by special blades. The special holder for the sheet material used with this device is also shown (Figure 2).

"Concerning the Question of Organization of Cleaning Clothing
Made of Cotton Fabric from Radioactive Contamination," by ✓
N. Yu. Tarasenko, Meditsinskaya Radiobiologiya, Vol 1, No 5, Sep-
Oct 56, pp 91-96

While working with radium, thorium, mesothorium, radiothorium, strontium-89, strontium-90, cesium-144, ruthenium-106, sodium-22, calcium 41, etc., and isotopes there is always danger of contamination of clothing; besides some radioactive substances may get into the internal organs. To prevent this danger two protective measures are described: establishment of safe levels of contamination, and control over these levels by dosimeters.

The method suggested is that clothes be tested for their radioactivity on wearing them (especially the sleeves and the front) and that after their wear they be sent in carefully labeled bags to central processing plants which are to be established in each city where institutions work with radioactive substances. Furthermore, the degree of contamination, i.e., Group 1, Group 2, or extremely contaminated, and type of contamination, i.e., alpha- beta- or gamma-contamination, also are to be labeled on the bag. It is also desirable to provide special laundries having areas that are especially designed to decontaminate footwear and accessories, such as gloves, filmy plastic suits, and gas masks.

Sbornik radiokhimicheskikh i dosimetricheskikh metodik (Collection of Radio-Chemical and Dosimetric Methods) Moscow, Medgiz, 1959. 459 p. Errata slip inserted. 9,000 copies printed.

Eds. (Title page): N.G. Gusev, U.Ya. Margulis, A.N. Marey, N.Yu. Tarasenko, Yu.M. Shtikkenberg; Ed. (Inside book): V.I. Labaznov; Tech. Ed.: A.I. Zakharova.

PURPOSE: This collection of articles is intended for physicists, sanitation and public health doctors, chemists and other specialists working in radioactive dosimetry.

COVERAGE: This work discusses the following subjects: (1) principles of organizing sanitation and dosimetric control in institutions where work is carried on with radioactive substances; (2) radio-chemical and chemical methods for determining certain radioactive substances in samples of air, water, soil and foodstuffs; (3) physical methods of measuring contamination of the air by radioactive gases and aerosols, and methods for determining the level of contamination of working surfaces, clothes and leather coverings; (4) methods

Card 1/ 11

Collection of Radio-Chemical and Dosimetric Methods

SOV/3589

of measuring external streams of x- and gamma-radiation, and methods of individual dosimetric monitoring; (5) Absolute and relative methods of measuring the activity of solid and liquid radioactive sources. There are four appendixes dealing with methods of calculating the total dosage from sources of ionizing radiation, units of activity, and doses from natural (background) radioactivity in the calcium of foodstuffs. Sanitary regulations observed during transportation, storage, and handling of radioactive substances are discussed, as well as the permissible level of ionizing radiation. The editors thank Yu.V. Sivintsev and D.P. Shirshov. References appear at the end of each chapter.
